ALIEN PROPERTY CUSTODIAN

LIGHT REFLECTOR AND ALLOY FOR MAK-ING THE SAME

Wilhelmus Kermsen and Francis Joseph Delves. Paris, France; vested in the Allen Property Cus-

No Drawing. Application filed August 30, 1939

This invention has for its object to provide a novel copper-aluminium alloy utilisable for making reflectors.

A further object of the invention is to provide a novel copper-aluminium alloy wherein the pro- 5 portions of the alloying constituents are such as to render said alloy easily malleable, moldable or workable.

A still further object of the invention is to flector made from said alloy and capable of reflecting pure orange-colored light rays or rays of long wave length, said reflector being mostly utilisable in photography or cinematography, for clinical work, for piercing fog and mist, for pro- 15 ored light rays. jecting anti-dazzling beams or for numerous other purposes.

With these and such other objects in view as will incidentally appear hereafter, the invention comprises the novel features or character- 20 istics that will now be described and pointed out in the appended claims.

According to the invention, the novel alloy comprises, by weight, from 89.50% to 92.50% of substantially pure copper and from 10.50% to 25 7.50% of substantially pure aluminium. The proportions of the alloying constituents may vary within these limits but the most suitable or optimum proportions for obtaining an easily malleable and workable alloy capable, when shaped 30 into the form of a reflector, to provide a surface that will reflect exclusively orange-colored rays are as follows:

Copper _____ 90.05 35 proved light reflector may be suggested, and this Aluminium_____ 9.95

Advantageously the copper aloyed to the aluminium is refined copper or cupric copper as produced by electrolysis.

According to the invention moreover, the improved reflector is made entirely of the aforesaid copper-aluminium alloy, for example in the form of a solid plate or panel, or has its light reflecting surface or wall constituted exclusively 45 by said alloy. When manufacturing the reflector, any alloy having the respective proportions by weight of copper and aluminium as above stated may be used with advantage. However, in order to obtain pure orange-colored 50 light (as verified by spectral observation or analysis) an alloy containing 90.05% of copper and 9.95% aluminium should be used. If such proportions by weight are altered within the given

still satisfactory especially if the optimum proportions of the alloying constituents are approximated.

The property of reflecting light rays of long wave length and particularly orange-colored rays renders the improved reflector made of a copperaluminium alloy as above described particularly valuable as a reflector in photography or cinematography (either for taking or for projecting provide a reflector and particularly a light re- 10 moving pictures) also for surgical or clinical work and for the construction of motor car lamps or any other similar purposes because, as it is well known, orange-colored rays are non-dazzling and less detrimental to human eyes than white-col-

> Furthermore, the property of rendering the reflected light rays capable of satisfactorily passing without diffraction through a heavy and dense mist or fog renders the improved reflector most valuable as a motor car lamp reflector or any other type of reflector as it facilitates traffic on roads in misty or foggy weather.

> Moreover, this valuable property may be used with success in reflectors or projectors for the navy, anti-aircraft purposes, large mirrors for in industrial purposes, ship beacons, projectors for locomotives and railway traffic, aviation, landing grounds, air signalisation devices, light houses, photography and cinematography purposes, street and road signalisation devices, also for street or road lighting, home lighting, workshop and factory lighting, theater stages, open air theaters, artistic lighting for buildings, advertising signs, etc. Many other fields of application of the imreflector can be produced according to any suitable shape and dimensions to suit any use what-

For producing the alloy of which the improved reflector can be made, pure copper in the selected quantity should be heated in a suitable receptacle to about 1160° C, to melt it. The receptacle containing the molten copper should then be withdrawn from the furnace and the copper allowed to cool to approximately 950° C. Aluminium in the form of small pieces, fragments, chips or scrap preliminarily heated to about 150° C. should then be added to the copper whereafter the two metals should be mixed to become alloyed. The alloy thus produced may be poured or cast into suitable ingot moulds, preferably made of earthen ware.

If the improved reflector is used for example for surgical work, in photography or cinematogscale, the results will be less perfect while being 55 raphy, in a motor car lamp or any other similar

purposes, its reflecting surface should be perfectly smooth and polished, the outline of said reflector being of suitable shape, for instance of a parabolic shape for imparting perfect parallelism to a beam of light rays emanating from an electric bulb or other source of light located at the focus. The transparent panel fitted in the hinged door of the casing of a lamp for motor cars should be made advantageously of a colorless glass. The rim in which such a glass panel 10 is fitted may be made of the same alloy as the reflector. If such is not the case, the said rim should be so located outside the periphery of the reflector as to have no influence on the beam of reflected light rays.

For use in photography or cinematography or for clinical work, for the construction of motor car lamps or any other similar purposes, the source of light of suitable power located at the focus of the reflector made of the copper-aluminium alloy as above-stated may be provided advantageously with a forwardly located screen or shield of the same metal as the reflector capable of throwing back the rays emitted by the said source of light towards the wall of the reflector. Such a screen or shield may be constituted for instance by a coating applied to the front portion of the glass wall of an electric bulb of the usual type, if such a source of light is used.

No constructional obstacle must be left inside the lamp that would interfere with the proper path of the light rays reflected by the improved 15 reflector.

WILHELMUS HERMSEN, FRANCIS JOSEPH DELVES.
